Site Licence Conditions for Schools

A school (or other recognised educational institution) may store the disk contents in multiple computers (or other data retrieval systems) to facilitate the following usages of the disk contents:

1. School staff may print and/or photocopy unlimited copies at one school and campus only, for use by students enrolled at that school and campus only, for non-profit, educational use only.

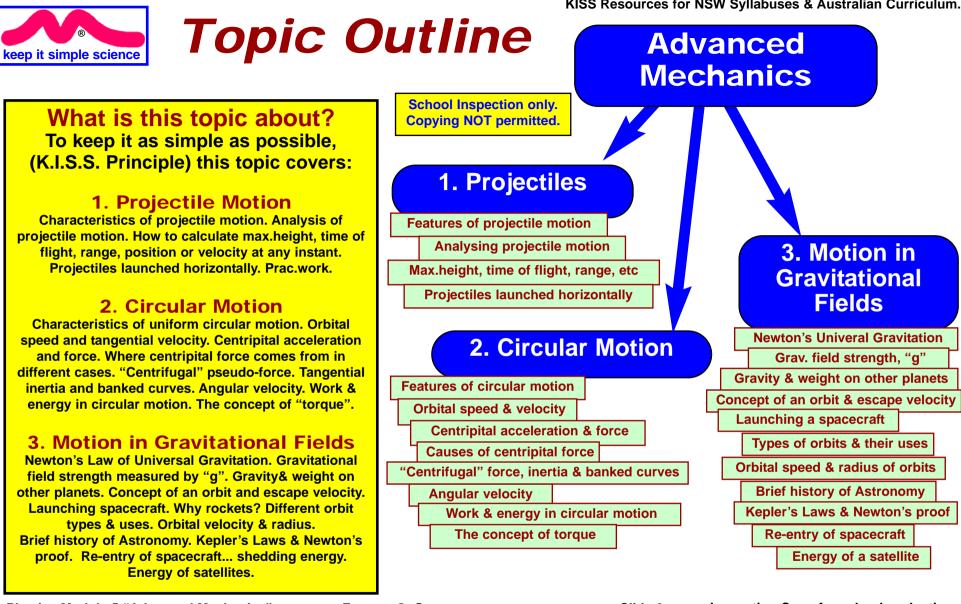

2. School staff may display the disk contents via computer networks, or using projectors or other display devices, at one school and campus only, for viewing by students enrolled at that school and campus only, for non-profit, educational use only. 3. School staff may allow students enrolled at that school and campus only to obtain copies of the disk files and store them in each student's personal computer for non-profit, educational use only.

IN THIS CASE, THE SCHOOL SHOULD MAKE PARTICIPATING STUDENTS AWARE OF THESE SITE LICENCE CONDITIONS AND ADVISE THEM THAT FURTHER COPYING OR DISTRIBUTION OF KISS FILES BY STUDENTS MAY CONSTITUTE AN ILLEGAL ACT.

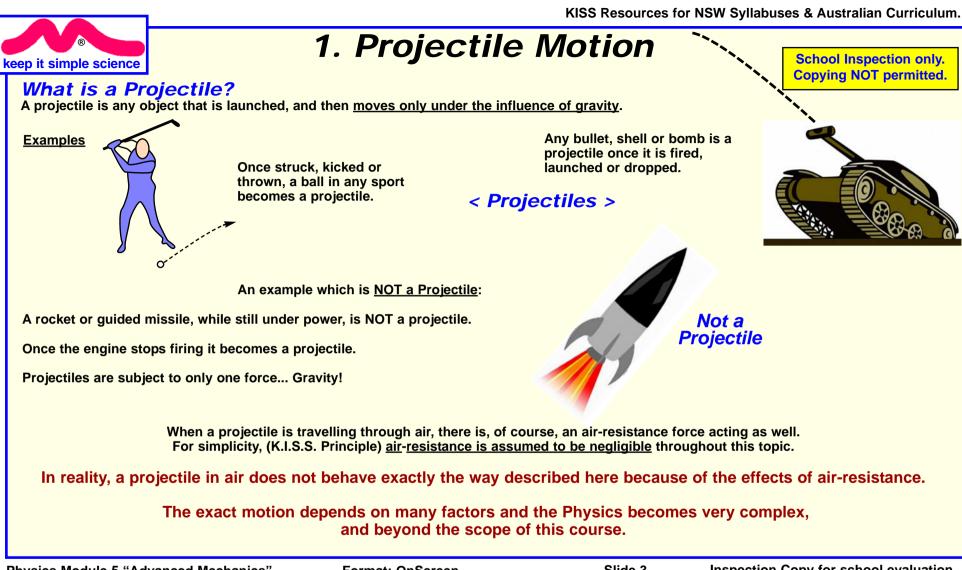

4. The KISS logo and copyright declaration must be included in every usage of KISS Resources.

5. NO time limit applies to the use of KISS Resources when used in compliance with these conditions.

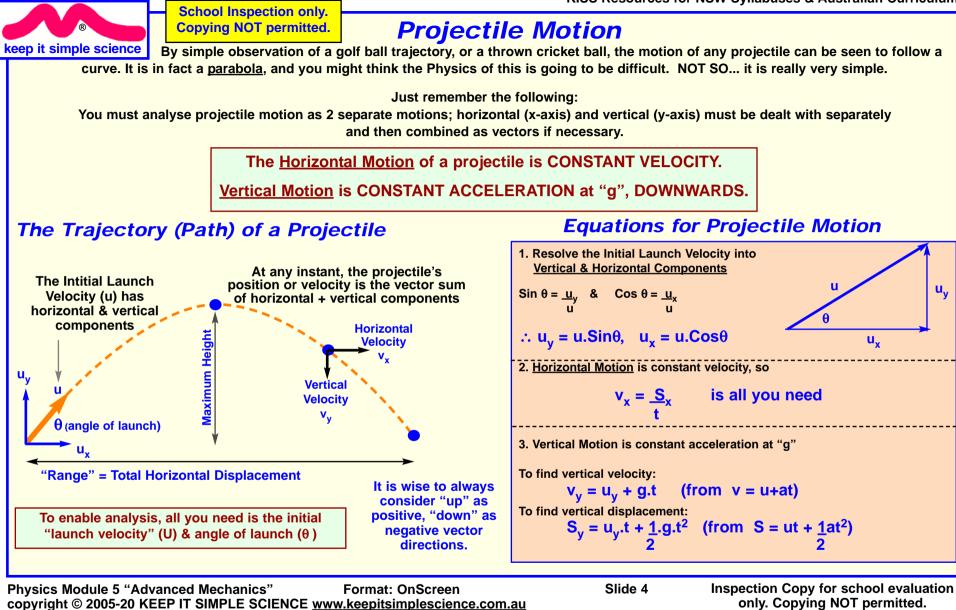

Please Respect Our Rights Under Copyright Law

Projectiles Launched Horizontally

A common situation with projectile motion is when a projectile is launched horizontally, as in the following example.

This involves half the normal trajectory.

The observation to make is whether or not the 2 objects hit the ground at the same time. Discuss the result.

Discusssion / Activity 1

The following activity might be for class discussion, or there may be paper copies for you to complete. If studying independently, please use these questions to check your comprehension before moving on.

Projectiles

Student Name

1. What is a "projectile"?

School Inspection only. Copying NOT permitted.

- 2. For a projectile launched on or near the surface of the Earth:
- a) what is the shape of the path it follows?
- b) at what angle will the maximum range be achieved?
- c) to analyse the Physics of a projectile, what is the "key" first-step? (given initial velocity & launch angle)

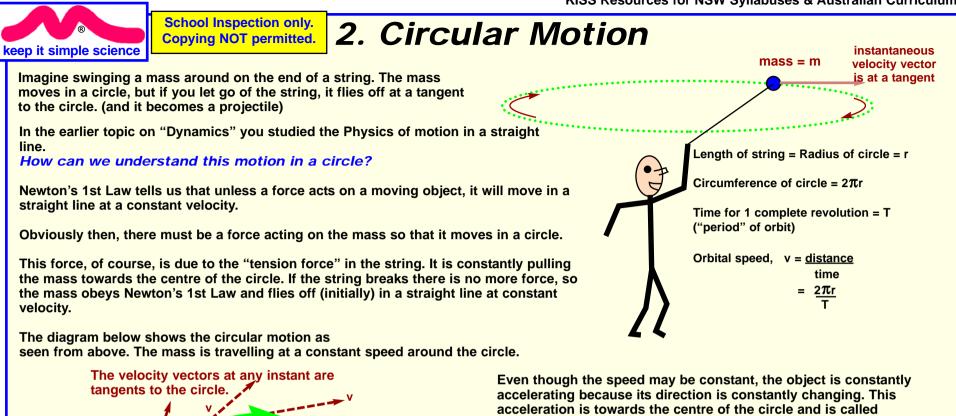

d) what is the "key" characteristic of the horizontal velocity?

e) describe the "key" characteristic of the vertical motion.

f) what is the instantaneous vertical velocity at the point of maximum height?

3. Give an outline of how the answer to 2(f) is vital to determining the values of max. height and range.

4. Imagine firing a gun horizontally across an open, flat plain. At the same instant that the bullet leaves the barrel, the empty shell casing is ejected horizontally from the gun. Which hits the ground first, the bullet or the casing? Explain.

The force causing the turning is Path of a always toward the centre of the mass in circle.This is called circular "Centripetal" force motion

Format: OnScreen Physics Module 5 "Advanced Mechanics" copyright © 2005-20 KEEP IT SIMPLE SCIENCE www.keepitsimplescience.com.au

"centripetal acceleration".

The force causing this acceleration is called "centripetal force" and is always directed to the centre of the circle.

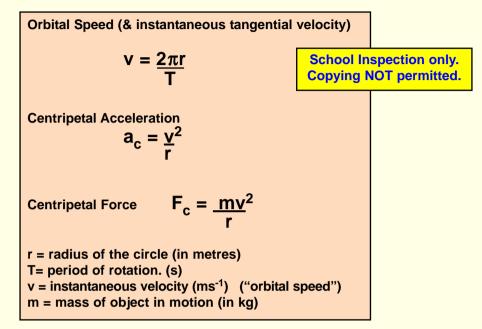

In the case of our mass on a string, the centripital force is the tension in the string. In the case of a car turning a circular corner, the centripital force is due to friction between the tyres and the road. In the case of a satellite in circular orbit, the force is due to gravity.

The <u>velocity vector</u> is constantly changing, but at any instant it is a tangent to the circle, and therefore, at right angles to the acceleration and force vectors.

Slide 11

Equations of Circular Motion

Example Problem

A 100g ball is being swung in a circle on a string of length 1.50m. It completes one "orbit" every 0.25s. Calculate:

- a) its orbital speed.
- b) the centripetal acceleration.
- c) the tension force in the string.

Solution

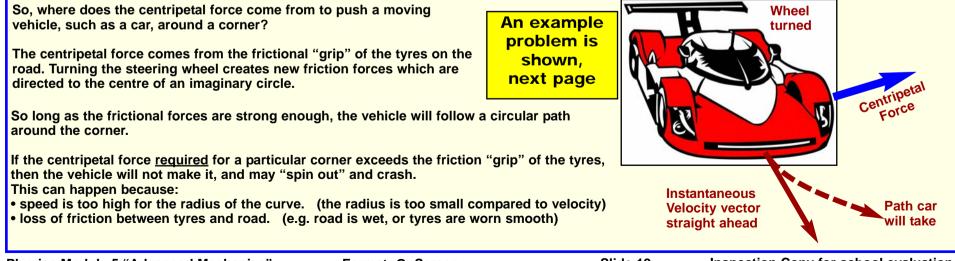

a) $v = \frac{2\pi r}{T} = 2 \times \pi \times 1.50 / 0.25$ T = 37.7 ms⁻¹.

b)
$$a_c = \underline{v}^2 = 37.7^2 / 1.50 = 948 \text{ ms}^{-2}.$$

c)
$$F_c = \frac{m v^2}{r} = 0.100 \times 37.7^2 / 1.50$$

= 94.8 N
(It had better be a strong string... F_c is about 10g

Circular Motion of Vehicles Turning Corners

Physics Module 5 "Advanced Mechanics" Format: OnScreen copyright © 2005-20 KEEP IT SIMPLE SCIENCE <u>www.keepitsimplescience.com.au</u> Slide 12

Example Problem (from previous page) The maximum frictional force possible from <u>each</u> <u>tyre</u> of this 750kg car is 5,000 N.

What is the maximum speed that the car can go around a circular curve with a radius of of 40m?

Solution

Max. Force possible from 4 tyres = 4x 5,000 = 20,000N Centripetal Force cannot exceed this value.

$$F_c = m v^2 / r$$
, so $v^2 = F_c r / m$
= 20,000 x 40 / 750
 $v^2 = 1067$

Centrifugal Forces & Banked Corners

"Centrifugal Force" is the <u>apparent</u> force that objects <u>seem to</u> experience when travelling around a curve, such as happens in circular motion. For example, we are all familiar with loose objects on the dashboard sliding to the left as our car turns a curve to the right. We would say that "centrifugal force pushed them towards the outside of the curve".

In fact, centrifugal force is a "pseudo-force" which arises due to inertia. It seems real when you are inside the turning car, but when analysed from a non-accelerating position (eg measuring the Physics from a stationary over-pass as the car travels under you) the only <u>real force</u> acting on the car (and contents) is <u>centripetal force</u> causing acceleration towards the centre of the circle.

The loose object on the dashboard has insufficient friction to stay attached to the car, so its inertia (Newton's 1st Law... tendency to continue travelling in a straight line) takes over. It actually tries to fly off at a tangent to the curve, but from within the car this seems to be an outwards push from a force we call "centrifugal".

The force is fake, but the inertia is real. On a bicycle at speed, the rider always "leans into the curve" to conteract the outward (actually tangential) inertia.

On a curve on a horizontal track, this inward lean can cause the rider to fall because the side-wall of the tyres comes into contact with the road surface and it may lack the friction to hold on at high speed.

Banking the curve up at an angle allows the rider to lean into a curve at high speed while still keeping the tyre tread in full frictional contact. Not only are cycle velodromes "banked", but so are well-made roadways and railways. Aircraft bank to turn, too. It's all about maintaining friction (or aircraft "lift") so centripetal force "pulls" you around the corner.

Physics Module 5 "Advanced Mechanics" Format: OnScreen copyright © 2005-20 KEEP IT SIMPLE SCIENCE <u>www.keepitsimplescience.com.au</u> Slide 13

Orbital Speed & Angular Velocity

School Inspection only. Copying NOT permitted.

Angular Velocity

When analysing circular motion, sometimes it is useful to measure the angle through which an object moves (measured from the centre of the circle) per unit of time, rather than measuring the distance travelled per unit of time.

For example, if you are observing a satellite pass overhead in the night sky, it is not easy to measure its velocity because (for instance) you don't know how high up it is and therefore you cannot measure distance travelled per second. BUT you can measure the angle it moves through per second.

For convenience when working with circles, the angles are always measured in <u>radians</u>, not degrees. (If not familiar with radians, note that 1 rad. \cong 57.3° because, by definition, there are 2π radians in a full circle 360°.) The convenience of using radians should become clear to you soon.

Angular Velocity

The angular velocity of an object in circular motion can be defined as the "angular change of position (displacement) per unit of time" when viewed from the centre of the circle. The symbol used for angular velocity is the (lower case) Greek letter omega (ω).

$$\omega = \Delta \phi_{t}$$

where $\Delta \phi$ is the change in the angle (in radians) and "t" is the elapsed time in seconds. The units for angular velocity are radians per second (rad.s⁻¹)

This is the formula presented in the syllabus and your HSC Data Sheet. However, it may be more informative to consider this concept as follows:

Imagine an object in circular motion. To travel one complete revolution, its angular displacement is 2π radians (360°). The time it takes for one revolution ("period") is "T" seconds.

Therefore, 0

 $\omega = \underline{\Delta \phi}_{t} = \underline{2\pi}_{T}$

This allows us to derive an alternate set of equations to apply to problems on circular motion.

Study the material at right, then

Try Worksheet 4

Physics Module 5 "Advanced Mechanics" Format: OnScreen copyright © 2005-20 KEEP IT SIMPLE SCIENCE www.keepitsimplescience.com.au

Slide 14

Inspection Copy for school evaluation only. Copying NOT permitted.

 $V = \frac{2\pi r}{T} \quad \text{but } \omega = \frac{2\pi}{T} \quad \text{so } V = \omega r$ $Centripetal \ Acceleration$ $a_{c} = \frac{v^{2}}{but} \quad v = \omega r$ $so \ a_{c} = \frac{\omega^{2} r^{2}}{\kappa} = \omega^{2} r$ $Centripetal \ Force$ $F_{c} = \frac{mv^{2}}{r}$

Substituting as above gives $F_c = m\omega^2 r$

Example Problem

A 250g ball is being swung around on a string which is 2.5m long. Its period of rotation is 1.25s.

- a) Find its angular velocity.
- b) What is the centripetal force in the string?
- c) What is the orbital speed?

Solution

$$\omega = \frac{2\pi}{T} = 2\pi / 1.25 = 5.03 \text{ rad.s}^{-1}$$

b)
$$F_c = m\omega^2 r = 0.250 \text{ x} (5.03)^2 \text{ x} 2.5$$

= 15.8 N

Work Done in Circular Motion

How much work is done by the centripetal force during circular motion?

You will recall that "work" is done when a force acts over a distance and that the amount of work is equivalent to the energy applied or used.

W = F.S

However, you may also recall that the displacement in this equation must be in the direction of the force.

The Concept of Torque

rotation

...and now for something completely different!

At this point the syllabus specifies that you must learn about another situation where an object may rotate in a circle. However, this rotation has nothing to do with "circular motion" involving centripetal force.

Instead, here we will consider the motion which occurs when one or more forces act. not towards the centre, but (usually) on the line of a tangent to the circle.

Pivot point or "fulcrum"

Let's begin with a simple example: a see-saw.

Basically, this is a rigid beam which is able to rotate around its pivot point, or "fulcrum". To begin with, it is perfectly balanced and motionless.

If you place a weight on one end the see-saw experiences a "turning moment" or "torgue" and begins to rotate.

Force

In the case of a see-saw. it won't go far because it will hit the ground, but in the case of many mechanical devices, the bar can continue to rotate in a circle if the force continues to act

Slide 15

Inspection Copy for school evaluation only. Copying NOT permitted.

School Inspection only. Copying NOT permitted.

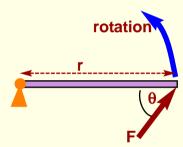

In circular motion, the centripetal force acts towards the centre of the circle. Since the revolving object always stays the same distance (= the radius) from the centre, then there is NO DISPLACEMENT in the direction of the force.

Therefore, the work done is zero!

In circular motion, no work is done by the centripetal force and no energy change occurs. This is why a planet in orbit can remain that way for ever, without running out of energy... no work is being done.

Calculating Torque

A force acts on the end of a rod or bar at distance "r" from its pivot point. (We use "r" because that distance is the radius of the circle it will turn around.) The force acts at angle θ as shown. Then:

 $\tau = r.F.sin\theta$

 τ = torque on the system, in newton-metres (Nm).

- r = distance from pivot to point where force is applied, in metres (m).
- F =force, in newtons (N).

Note that when $\theta = 90^{\circ}$, $\sin \theta = 1$. This means that maximum torque occurs when the force acts at right angles to the bar. If $\theta = 0^{\circ}$, torque is zero.

The symbol for torgue is the Greek letter "tau", T.

An example problem is shown, next page

The Concept of Torque (cont.)

edge.

Everyday examples of applying torque include:

co-incidence that the units of measurement are the same.

 $P = \tau . \omega$ (Power = torque x angular velocity)

• winding the handle on a fishing reel, or winch.

topic when electric motors are covered.

Is Torque the Same as "Work"?

to energy until multiplied by the rotation rate.

change) is actually given by

• pushing a door open on its hinges. If you push on the door at a point close to the

If the shaft of the handle is longer, you get more torgue and the job is easier.

equivalent to energy, so a newton-metre of work is equal to a joule of energy.

hinges, you need much more force to get the same torgue as pushing at the outside

The concept of torque is especially important with motors. It will be re-visited in a later

The unit of torque is a newton-metre. This is the same unit as Work. (W = F.S) Work is

But wait! This does NOT work. Torgue is NOT the same as energy and it is simply a

Torque is a measure of the rate of change of angular momentum and is not equivalent

We are NOT going there, but for the petrol-heads, the torque of a car engine IS related

to how powerful it is. An engine's power is described as "(number of) kilowatts at

(number of) RPM". RPM is "revolutions per minute". Engine power (power is rate of energy

School Inspection only. Copying NOT permitted.

Example Problems

1. A rigid bar has a pivot point at one end and is 3.0m long. It can rotate in a horizontal plane and for simplicity, friction and the weight of the bar itself are taken to be zero.

Find the magnitude of the torque if:

a) a force of 10N is applied at right angles, at a point halfway along the bar.

b) The same force is applied at the end of the bar.c) The same force is applied just 10cm from the pivot.

d) A force of 20N is applied to the end of the bar at an angle of 30°.

Solutions

a) $\tau = r.F.sin\theta = 1.5 \times 10 \times sin90 = 15 \text{ Nm}.$

- b) $\tau = r.F.sin\theta = 3.0 \times 10 \times sin90 = 30$ Nm.
- c) $\tau = r.F.sin\theta = 0.1 \times 10 \times sin90 = 1.0$ Nm. (note the effects of distance from the pivot)

d) $\tau = r.F.sin\theta = 3.0 \times 20 \times sin30 = 30$ Nm.

(Compare (d) with (b) to note the effect of angle)

Discusssion / Activity 2

The following activity might be for class discussion, or there may be paper copies for you to complete. If studying independently, please use these questions to check your comprehension before moving on.

Circular Motion

1. For an object in circular motion, in what direction is the:

a) instantaneous velocity?

b) centripital acceleration?

c) centripital force?

Student Name

School Inspection only. Copying NOT permitted.

2. Explain how an object in circular motion can be described as having a constant speed, but also a constant acceleration? Isn't this a contradiction?

3. Derive from first principles, a mathematical expression for: a) the orbital speed.

b) the angular velocity.

c) Combine these 2 expressions to form a formula showing how orbital speed and angular velocity are related.

- 4. What force provides the centripital acceleration in the case of:
- a) an orbiting satellite?
- b) a car turning a corner?
- c) a ball being twirled on a string?

3. Motion in Gravitational Fields

Newton's Universal Gravitation

School Inspection only. Copying NOT permitted.

Gravitational Fields

Every mass acts as if surrounded by an invisible "force field" which <u>attracts</u> any other mass within the field. Theoretically, the field extends to infinity, and therefore every mass in the universe is exerting some force on every other mass in the universe... that's why it's called <u>Universal</u> Gravitation.

Newton's Gravitation Equation

It was Isaac Newton who showed that the strength of the gravitational force between 2 masses: • is proportional to the product of the masses, and • inversely proportional to the square of the distance between them.

He came up with this idea in 1666 as a way to solve a long-standing problem in Astronomy to do with "Kepler's Laws of Planetary Motion".

More about that later!

Effects of Mass & Distance

How does the Gravitational Force change for different masses, and different distances?

Imagine 2 masses, each 1kg, separated by a distance of 1 metre.

$$_{G} = \frac{GMm}{r^{2}} = \frac{G \times 1 \times 1}{1^{2}} =$$

Effect of masses

Now imagine <u>doubling the mass</u> of one object: $F_G = GMm = G \times 2 \times 1 = 2G$ (Twice the force)

What if both masses are doubled? $F_G = GMm = G \times 2 \times 2 = 4G$

Effect of Distance

Go back to the original masses, and double the distance: $F_{c} = GMm = G \times 1 \times 1 = G$ (1/4 the force)

$$F_{G} = \frac{GMm}{r^{2}} = \frac{G \times 1 \times 1}{2^{2}} = \frac{G}{4}$$
 (1/4 the fo

Gravitational Force shows the "Inverse Square" relationship... triple the distance = one ninth the force 10 x the distance = 1/100 the force, etc.

Physics Module 5 "Advanced Mechanics" Format: OnScreen copyright © 2005-20 KEEP IT SIMPLE SCIENCE www.keepitsimplescience.com.au

 $F_G = GMm r^2$

 $F_{G} = \text{Gravitational Force, in N.}$ $G = \text{``Universal Gravitational Constant''} = 6.67 \times 10^{-11}$ M & m = the 2 masses involved, in kg. r = distance between M & m (centre to centre) in m. $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$ $F_{and between M \& m (centre to centre) in m.$

$$F_{G} = \frac{GMm}{r^{2}}$$

$$= \frac{6.67 \times 10^{-11} \times 5.97 \times 10^{24} \times 80}{(6.37 \times 10^{6})^{2}}$$

$$= 785 \text{ N.}$$
is of course the person's weight!

This is, of course, the person's weight! ... and sure enough

Solu

(4X the force)

Try Worksheet 6

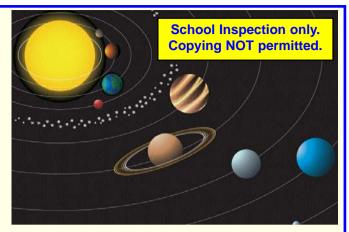

Universal Gravitation & Orbiting Satellites

It should be obvious by now that it is F_{G} which provides the centripetal force to hold any satellite in its orbit.

Not only does this apply to artificial satellites launched into Earth orbit, but for the orbiting of the Moon around the Earth, and of all the planets around the Sun.

Our entire Solar System is orbiting the Galaxy because of gravity, and whole galaxies orbit each other. Ultimately, gravity holds the entire universe together, and its strength, compared to the expansion of the Big Bang, will determine the final fate of the Universe.

The Gravitational Field Strength, "g"

In earlier topics you learnt that "g" is the acceleration due to gravity. That's fine, but there is another way to think of it. Look again at example 2 on the previous page.

From that problem we can say that:

<u>weight force</u> = gravitational force mg = GMm / r^2

Now imagine placing a 1kg mass at a point within the gravity field of a planet with mass "M".

If m = 1 in the equation above, then: $g = GM / r^2$

This can be interpreted as the <u>strength of the gravitational field</u> at that point, because it defines the effect of the field on a "<u>test mass</u>" of 1 unit (kg).

(Compare this idea to how the Electric Field strength was defined in a previous module.)

So, "g" is both the strength of the grav. field (measured in $N.kg^{-1}$) at a given point AND it is the acceleration due to gravity (ms⁻²) at that point.

We tend to think of gravity as being the same everywhere, but that is only because we are always on, or very close to, the Earth's surface where $g = 9.8 \text{ N.kg}^{-1}$ or ms⁻².

However, the equation at left means that the value of "g" depends on the mass of the planet you are on AND how far you are from its centre.

Here on the surface of Earth we are $r_E = 6.371 \times 10^6$ m from the centre of a mass of $M_F = 6.0 \times 10^{24}$ kg.

Substituting this gives

```
g = 6.67 \times 10^{-11} \times 6.0 \times 10^{24} / (6.371 \times 10^{6})^2
= 9.86 ms<sup>-2</sup>.
```

(Discussion: why doesn't this agree exactly with standard data?)

Go up 1,000 km above the surface and $g = 7.4 \text{ ms}^{-2}$.

If the Earth became denser and shrank so that the surface was 1,000km lower, (but same mass) then surface gravity would be $g = 13.9 \text{ ms}^{-2}$.

However, if you go lower by digging a hole, "g" actually <u>decreases</u>. As you go deep into the Earth, some of its mass is above you, attracting you upwards.

Try Worksheet 7 parts (a)-(h) only

At the centre of the Earth g = zero!

Slide 19

Gravity and Weight on Other Planets

School Inspection only. Copying NOT permitted.

We are so used to the gravity effects on Earth that we need to be reminded that "g" is different elsewhere, such as on another planet in our Solar System.

Since "g" is different, and weight force F = mg it follows that things have a different weight if taken to another planet.

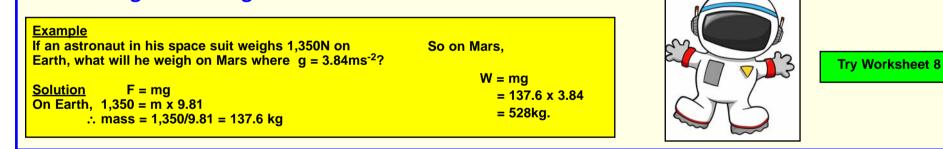

Here are values of "g" on the surface of some other planets. (Good luck finding the surface of Jupiter if you go there!)

<u>Planet</u>	g	g
(ms ⁻²)	(as multipl	e of Earth's
Earth	9.8	1.00
Mars	3.8	0.39

Isaac Newton and Orbiting

Once Isaac Newton had developed the Maths and discovered the laws of motion and gravity, he thought about Projectile Motion.

Newton imagined a cannon on a very high mountain, firing projectiles horizontally with ever-increasing launch velocities. The faster each ball is launched, the further it flies before hitting the ground.

But then	if the launch velocity is high enough, the projectile can escape from the	r = Radius of planet
	Earth's gravity completely.	Note that:
		 The mass of the projectile of mass, need the same vel second!
EARTH	at the right velocity, the projectile	The Escape Velocity dependence

Placing a Spacecraft into Earth Orbit

A projectile needs an enormous velocity to escape from the Earth's gravitational field... about 11 km per second. Think of a place 11 km away from you, and imagine getting there in 1 second flat!

What about Newton's idea of an orbiting projectile?

If it is travelling at the right velocity, a projectile's down-curving trajectory will match the curvature of the Earth, so it keeps falling down, but can never reach the surface. A projectile "in orbit" becomes a "satellite".

It can be shown that to achieve orbit, the launch velocity required is less than escape velocity, but still very high... about 8 km per second. How is this velocity possible?

In a 19th century novel, author Jules Verne proposed using a huge cannon to fire a space capsule (including human passengers) into space.

The problem with this idea is the rate of acceleration to go from zero to orbital velocity in the very short time it takes to fire a cannon. A fit, trained astronaut can tolerate sustained forces of "5g", but anything above about "10g" is life-threatening. Jules Verne's cannon astronauts would have suffered forces of about 200g... instantly fatal.

That's why we use rockets, not cannons. A large rocket can produce a steady acceleration at a "g-force" which is acceptable for trained astronauts, over the 10 minutes (or so) that it takes to reach orbit. If you're wondering why we don't use jet engines, or similar, you need to remember that there is no air (with oxygen to burn the fuel) in space. Rockets carry their own oxidisers plus fuel and so do not need air. In fact, of course, they work better in space where there is no air resistance.

nitted. A Brief History of Rocketry

Simple <u>solid-fuel</u> (e.g. gunpowder) rockets have been used as fireworks and weapons for over 500 years.

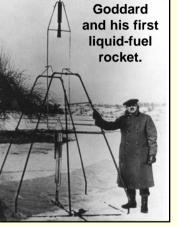

Over 100 years ago, the Russian <u>Tsiolkovsky</u> (1857-1935) was the first to seriously propose rockets as vehicles to reach outer space. He developed the theory of multi-stage, liquid-fuel rockets as being the only practical means of achieving space flight.

The American <u>Robert Goddard</u> (1882-1945) developed rocketry theory futher, but also carried out practical experiments including the first liquid-fuel rocket engine.

Goddard's experiments were the basis of new weapons research during World War II, especially by Nazi Germany.

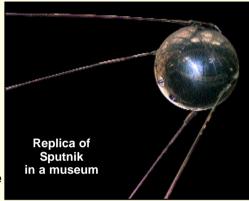

Wernher von Braun (1912-1977) and others developed the liquidfuel "V2" rocket to deliver explosive warheads at supersonic speeds from hundreds of kilometers away.

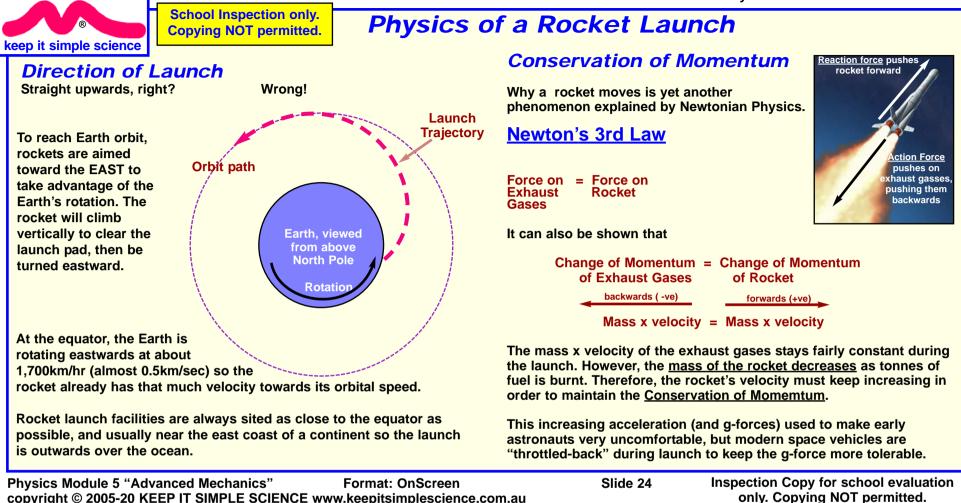

At the end of the war many V2's, and the German scientists who developed them, were captured by either the Russians or the Americans. They continued their research in their "new" countries, firstly to develop rockets to carry nuclear weapons (during the "Cold War") and later for space research.

The Russians achieved the first satellite ("Sputnik" 1957) and the first human in orbit, and the Americans the first manned missions to the Moon (1969).

Since the 1970's, the use of satellites has become routine and essential to our communications & research, while (unmanned) probes have visited every other planet in the Solar System, plus an asteroid and a comet.

Low-Earth Orbit

As the name suggests, this type of orbit is relatively close to the Earth, generally from about 200km, out to about 1,000km above the surface.

For any satellite, the closer it is, the faster it must travel to stay in orbit. Therefore, in a Low-Earth Orbit a satellite is travelling quickly and will complete an orbit in only a few hours.

A common low orbit is a "<u>Polar Orbit</u>" in which the satellite tracks over the north and south poles while the Earth rotates underneath it.

centripital force which keeps a satellite in orbit.

Geo-Synchronous Orbits

are those where the <u>period of the satellite</u> (time taken for one orbit) is exactly the same as the Earth itself... 1 day.

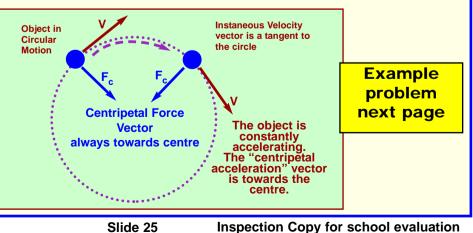

If the satellite orbit is directly above the equator, the satellite is also "<u>geo-stationary</u>", meaning that it is always directly above the same spot on the Earth, and seems to remain motionless in the same position in the sky. It's not really motionless, of course, but orbiting around at the same angular velocity as the Earth itself.

Geostationary orbits are above the equator, and have to be about 36,000km above the surface in order to have the correct orbital speed.

Being so far out, these satellites are not much good for photographs or surveys, but are ideal for communications. They stay in the same relative position in the sky and so radio and microwave dishes can be permanently aimed at the satellite, for continuous TV, telephone and internet relays to almost anywhere on Earth.

Three geostationary satellites, spaced evenly around the equator, can cover virtually the whole Earth with their transmissions.

From previous page...

Solution

r

a) First, find the true radius of the orbit, and get everything into S.I. units: Radius of orbit = $200,000 + 6.37 \times 10^6 = 6.57 \times 10^6 \text{m}$ Period = $1.47 \text{hr} = 1.47 \times 60 \times 60 = 5.29 \times 10^3 \text{ sec.}$ $y = 2\pi r = 2 \times \pi \times 6.57 \times 10^6 / 5.29 \times 10^3 = 7.80 \times 10^3 \text{ms}^{-1}$.

T

$$F_{a} = mv^{2} = 250x (7.80x10^{3})^{2} / 6.57x10^{6}$$

= 2,315 = 2.32 x 10³ N.

Try Worksheet 10

The satellite is travelling at about 8 km/sec, held in orbit by a gravitational centripetal force of about 2,300N.

Satellites, Planets & Moons

School Inspection only.

Copving NOT permitted.

So far, we have used the word "satellite" only for human-made spacecraft in Earth orbit.

However, don't forget that all the planets of the Solar System are satellites of the Sun and that the Moon is a natural satellite of Earth. Most of the other planets have moons (some have dozens) and these are satellites of their "primary"... the body they orbit around.

Orbital Speed & Radius

 $F_c = F_G$ or $\underline{mv}^2 = \underline{GMm}_{r^2}$

Since we know that the centripetal force is due to the gravitational force between the satellite and its "primary", we can say:

 $v^2 = \underline{GM}$ so $v = \sqrt{\underline{GM}}$

What this means is, that for any given "primary" object, there is a relationship between the orbital speed of a satellite and the radius of the orbit.

To put it another way, for any given radius of an orbit, there is a certain orbital speed which "fits" that orbit. The relationship is inverse: a larger radius orbit results in a slower orbital speed and vice-versa.

For artificial satellites in Earth orbit, this means that low-level satellites must move very fast in their orbit, while those further out move more slowly.

Same thing for the planets in orbit around the Sun. Those closer to the Sun move faster, those further out move slower. This was first realised and measured by astronomers about 400 years ago and was the stimulus that caused Isaac Newton to get busy.

It will help your understanding if you know some background about what they knew back then, and what was the problem that Newton solved.

What does this mean?

A Brief History of Astronomy (to the time of Newton)

Ancient Beliefs

School Inspection only. Copying NOT permitted.

In ancient times, the Sun, Moon & stars were "The Heavens" and considered the home of Gods. The early Greeks were the first to attempt to explain things based on evidence, observation & calculation... ie scientifically.

Generally, it was believed that the Earth was the centre of the Universe and everything else revolved around us. There were some who realised that movements in the sky could also be explained if the Earth went around the Sun AND rotated on its axis. (if interested, research <u>Aristarchus</u>.) However, no-one could find evidence for movements of the Earth, so the "<u>Geocentric</u> <u>Model</u>" was accepted.

Throughout the Middle Ages, this idea was so prevalent that it was adopted by the Church as religious dogma... any other suggestions were <u>heresy</u> and punishable by torture & death.

Nicholas Copernicus (Polish. 1473 -1543)

The first modern suggestion that the Earth revolves around the Sun was published by Copernicus in a book released just as he died.

It was a <u>Heliocentric</u> model... Sun centred.

The accuracy of predicted motions of planets, etc. remained much the same as the Geocentric model, but this model was much simpler in its explanations. The Copernicus model was NOT immediately accepted at the time because:

• there was still no evidence that the Earth moved.

• the Church condemned the theory as heresy and banned the book.

Tycho Brahe (1546-1601 Danish)

Tycho built the most advanced observatory of that time to gather outstandingly accurate data (accurate for measurement <u>without</u> a telescope) of planetary movements.

Drawing of Tycho's Observatory

Physics Module 5 "Advanced Mechanics" Format: OnScreen copyright © 2005-20 KEEP IT SIMPLE SCIENCE www.keepitsimplescience.com.au

Tycho Brahe (cont.)

He favoured the geocentric model and hoped his observations would prove Copernicus wrong. However, this doesn't mean he accepted the ancient models either. His aim was to develop a new model, but he died before completing it.

He had jealously guarded his data from others, but when he died it went to his student Kepler.

Johannes Kepler (1571-1630 German)

Kepler fitted Brahe's extremely accurate data (especially of the movements of planet Mars) to the Copernicus model. He found it fitted, but only if the orbits were ellipses, not circles.

Eventually he proposed 3 "Laws of Planetary Motion", but could give no explanation of how or why the Earth and planets could orbit around the Sun. The Heliocentric idea was still NOT accepted widely. One of his "Laws" is detailed, next page.

Galileo Galilei (1564-1642 Italian)

About the same time as Kepler's Laws, (circa 1610) Galileo was the first to use a TELESCOPE to view the heavens.

His observations of Jupiter's moons, planet Venus and The Moon conflicted with the Geocentric model and supported the Heliocentric idea of Copernicus. He was arrested by the Church and forced to formally deny his findings, under threat of torture.

He was formally acquitted & forgiven by the Church 350 years later.

Slide 27

But $v = 2\pi r$

Kepler's "Law of Periods" & Newton's Proof

One of Kepler's "Laws of Planetary Motion" was a mathematical relationship between the <u>Period</u> of the orbit and its <u>Radius</u>:

```
r<sup>3</sup> α T<sup>2</sup> (Greek letter alpha (α) means "proportional to")
```

This means that

 $r^{3}_{T^{2}}$ = constant

School Inspection only. Copying NOT permitted.

This means that for every planet, the $(Radius)^3$ divided by $(Period)^2$ has the same value. Similarly, every satellite of the Earth would have the same value of r^3 / T^2 , but this value would be quite different to the value for the Sun's satellites. The ratio is different for each "primary".

Kepler's <u>Law of Periods</u> was discovered empirically... that is, it was discovered by observing the motion of the planets, calculated from Tycho's data. Kepler had no idea WHY it was so and could not prove mathematically that it was generally true.

For about 50 years, no-one could figure this out. Meanwhile, across Europe the power and control of the Church of Rome was being weakened by the spread of the Protestant movement.

In Protestant countries Science was flourishing and in England, a new generation of brilliant scientists had formed a scientific "club" called the "<u>Royal Society</u>". They became interested in solving the riddle of Kepler's Laws.

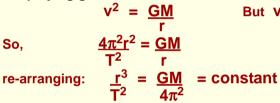

Encouraged by others, Isaac Newton (age 24) solved the problem. There is a legend that he was inspired by seeing an apple fall from a tree, but in fact he developed his famous 3 "Laws of Motion", invented a whole new method of Maths (now called "Calculus") and topped it off with his Law of Gravity... apples have nothing to do with such genius!

With his "Law of Universal Gravitation" he was able to prove the theoretical basis for Kepler's Law, as follows:

The Centripetal Force of orbiting is provided by the Gravitational Force between the satellite and the Earth, so

$$F_c = F_G$$
 or $\underline{mv}^2 = \underline{GMm}{r^2}$

Simplifying gives:

Example Problems next page

Since the right hand side contains all constant values, this proves Kepler's Law and establishes the Force of Gravity as the controlling force for all orbiting satellites, including planets around the Sun.

This proof explained Kepler's Laws and proved mathematically that the Heliocentric idea is correct. Newton's Gravity law fitted precisely with the Astronomical observations to explain how & why the Universe worked. Soon, new telescopic observations followed Galileo's work & eventually found the proof that the Earth was moving. Many consider that Galileo's observations & Newton's theories marked the beginning of modern Science.

From previous page...

Problem 1

In a previous problem, an Earth satellite 200km high had a period of 1.47 hrs. Use this to find the height of a geosynchronous satellite using Kepler's Law.

Solution

For the satellite above, (units are km & hours) $\frac{R^3}{T^2} = \frac{6.570^3}{1.47^2} = 1.31 \times 10^{11}$

According to the law of periods, ALL satellites of Earth must have the same value for R³/T²

So, for the geo-stationary satellite:
$$\frac{R^3}{T^2}$$
 = 1.31 x 10¹¹
So R³ = 1.31x10¹¹x (24.0)²
∴R = $\sqrt[3]{7.55x10^{13}}$ = 4.23 x 10⁴ km

This is approx. 42,000km from Earth's centre, or about 36,000km above the surface.

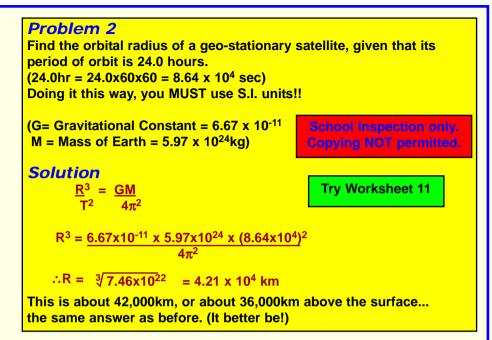

Note: When using Kepler's Law this way it doesn't matter which units are used, as long as you are consistent. In this example, km & hrs were used. You get the same answer with metres & seconds.

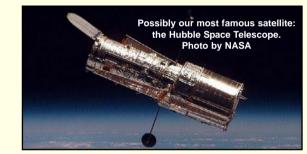

Decay of Low-Earth Orbits

Where does "Space" begin?

It's generally agreed that by 100km above the surface of the Earth the atmosphere has ended, and you're in outer space. However, although this seems to be a vacuum, there are still a few atoms and molecules of gases extending out many hundreds of kilometres.

Therefore, any satellite in a low-Earth orbit will be constantly colliding with this extremely thin "outer atmosphere". The friction or air-resistance this causes is extremely small, but over a period of months or years, it gradually slows the satellite down.

As it slows, its orbit "decays". This means it loses a little altitude and gradually spirals downward. As it gets slightly lower it will encounter even more gas molecules, so the decay process speeds up.

Once the satellite reaches about the 100km level the friction becomes powerful enough to cause heating and rapid loss of speed. At this point the satellite will probably "burn up" and be destroyed as it crashes downward.

Modern satellites are designed to reach their low-Earth orbit with enough fuel still available to carry out short rocket engine "burns" as needed to counteract decay and "boost" themselves back up to the correct orbit. This way they can remain in low-Earth orbits for many years.

School Inspection only. Copying NOT permitted.

Re-Entry From Orbit

Getting a spacecraft into orbit is difficult enough, but the most dangerous process is getting it down again in one piece with any astronauts on board alive and well.

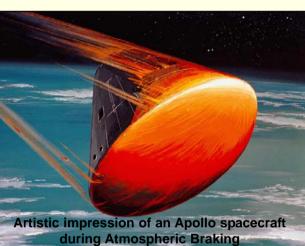

In orbit, the satellite and astronauts have a high velocity (kinetic energy) and a large amount of GPE due to height above the Earth. To get safely back to Earth, the spacecraft must decelerate and shed all that energy.

It is impossible to carry enough fuel to use rocket engines to decelerate downwards in a reverse of the lift-off, riding the rocket back down at the same rate it went up.

Instead, the capsule is slowed by "retro-rockets" just enough to cause it to enter the top of the atmosphere so that friction with the air does 2 things:

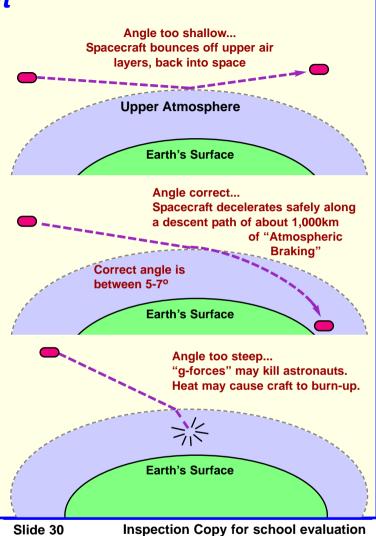

- cause deceleration of the capsule at a survivable rate of deceleration not more than (say) "5-g", and
- convert all the E_k and GPE into heat energy.

The trick is to enter the atmosphere at the correct angle.

Early spacecraft used "ablation shields", designed to melt and carry heat away, with the final descent by parachute. The Space Shuttle used high temperature tiles and high-tech insulation for heat protection, and glided in on its wings for final landing like an aircraft.

Energy of a Satellite

In a previous module you studied the relationship for any object on or near the Earth, that the change of Gravitational Potential Energy (GPE) is

School Inspection only. Copying NOT permitted.

 $\Delta U = ma\Delta h$

If an object is allowed to fall down, it loses some GPE and gains some other form of energy, such as Kinetic or Heat. To raise the object higher, you must "do work" on it, in

order to increase the amount of GPE it contains.

Notice that this equation calculates the CHANGE in GPE and assumes a constant value for "g" on or near the Earth's surface. For satellites this is useless.

Gravitational Potential Energy

For mathematical reasons, the point where an object is defined to have zero GPE is not on Earth, but at a point an infinite distance away. So GPE is defined as follows:

Gravitational Potential Energy is a measure of the work done to move an object from infinity, to a point within the gravitational field.

This definition has an important consequence:

it defines GPE as the work done to bring an object towards the Earth, but we know that you need to do work to push an object (upwards) away from Earth.

Therefore, GPE is, by definition, a negative quantity!

So, if you lift an object upwards against gravity, its GPE increases by becoming less negative. It's value might go from (say) -10 units to -5 units.

Physics Module 5 "Advanced Mechanics" Format: OnScreen copyright © 2005-20 KEEP IT SIMPLE SCIENCE www.keepitsimplescience.com.au

U = -GMm

- U = GPE in joules (J)
- G = Gravitational Constant (= 6.67×10^{-11})
- m = mass of object (kg)
- M = mass of Earth, or other planet (kg)
- r = distance from centre of the "primary" (m).

Example Problem

Compare the GPE possessed by a geosynchronous $(r = 4.2 \times 10^7 m)$ satellite of mass 500kg, with that of a 500kg satellite in low orbit 200km up. $(r = 6.571 \times 10^6 m)$

Solution

Geosynch, Satellite

Low Orbit Satellite

U = -GMm

- $= -6.67 \times 10^{-11} \times 5.97 \times 10^{24} \times 500 / 6.571 \times 10^{6}$
- $= -3.03 \times 10^{10} \text{ J}$ (-30,300,000,000)

The higher satellite has more GPE (about 6 times more) by virtue of being less negative in value.

Slide 31

Energy of a Satellite (cont.)

School Inspection only.

Copying NOT permitted.

Kinetic Energy in Orbit

You previously learned that

 $E_k = \frac{1}{2}mv^2$

but to work it out for a satellite it would be better to express it in terms of G, M, r, etc.

We begin the same way as we have before:

 $F_c = F_G$ or $\underline{mv}^2 = \underline{GMm}_r^2$

Multiply both sides by "r" and divide by 2 gives:

 $\frac{mv^2}{2} = \frac{GMm}{2r}$

The left side is the kinetic energy expression, so:

 $E_k = \frac{GMm}{2r}$

This means that a satellite in a higher orbit (r is larger) will have less E_k . That makes sense, because at higher orbits we know that its velocity is lower.

Total Energy of a Satellite

The total energy of the satellite is the sum of its kinetic energy plus its gravitational potential energy.

Total Energy = $E_k + U$ of a Satellite = GMm + -GMm 2r rFxpress with a common denominator: = GMm + -2GMm = GMm - 2GMm 2r 2r2r

The launch of the space shuttle carrying the Hubble Space Telescope in 1990.

Finish with Worksheet 13

Inspection Copy for school evaluation only. Copying NOT permitted.

Example Problem

How much energy is required to lift a 500kg satellite from a low orbit ($r = 6.571 \times 10^6$ m) up to a geosynchronous orbit? ($r = 4.2 \times 10^7$ m)

Solution

Total energy in low orbit $E_k + U = -\frac{GMm}{2r} = \frac{-6.67 \times 10^{-11} \times 5.97 \times 10^{24} \times 500}{2 \times 6.571 \times 10^6}$ $= -1.51 \times 10^{10} J$

Total energy in geosynch. orbit

$$E_{1} = -GMm = -6.67 \times 10^{-11} \times 5.07 \times 10^{24} \times 50^{-11}$$

$$\frac{2 \text{ Imm}}{2 \text{ r}} = \frac{2 \times 37 \times 10^{-2} \times$$

Try Worksheet 12

In the higher orbit, its total energy is increased (it is less negative). It has lost E_k (lower velocity) but gained GPE (more height).

The actual answer to the question is the difference between these values:

Energy required = $-2.37 \times 10^9 - (-1.51 \times 10^{10}) = 1.27 \times 10^{10} \text{ J}$

Discusssion / Activity 3

School Inspection only. Copying NOT permitted.

The following activity might be for class discussion, or there may be paper copies for you to complete. If studying independently, please use these questions to check your comprehension before moving on.

Motion in Gravitational Fields

Student Name

1. a) Given that the gravitational force on a mass (which is in a grav. field) is equal to the objects weight force at that point, derive an expression for "g", the acceleration due to gravity.

b) Arising from (a) comes another way to interpret the meaning of "g". Give an outline of this meaning.

2. Two important types of satellite orbits can be described as "geostationary" and "polar low-Earth". For each, describe the main features of each orbit and relate these features an an appropriate technological use of a satellite in such an orbit.

- 3. a) What was Kepler's "Law of Periods" about?
- b) Write a simple mathematical expression to summarise this law.
- c) Outline Newton's proof of the law.

d) What was the significance of this proof in the history of Science?

4. Why is the value of an object's gravitational potential energy always a negative quantity?
